Evaluation of binding affinities of single point mutations in the interleukin-2 receptor alpha-chain (IL2Ralpha) has been widely used as a model for studies on protein-protein interactions, binding sites of peptides and antibodies, and mechanisms of ligand recognition. However, no systematic report is available which compares the relative binding affinities of these single-site mutants. To investigate this we constructed and characterized a set of single-site mutants of IL2Ralpha and compared the binding affinities of these mutants to those of corresponding wild-type protein. Our results revealed that this approach is suitable for accurate evaluation of the binding affinities of mutations which directly affect the binding interface or subunit interface of the IL2Ralpha. These results are beneficial to a better understanding of the binding mechanisms of single point mutations and a variety of biophysical and structural techniques in which the role of receptor mutations in ligand binding and receptor function can be studied.
